

Future State (TO-BE) Process Design Document

End-to-End Salesforce CRM Transformation for

Customer Operations and Service Management

3.1 Salesforce Process Design

3.1.1 Architectural Principles

a. Centralized Data Management

In order to move away from fragmented tracking sheets, Salesforce is designated as the authoritative single source of truth within the organization. The architecture leverages native data loading protocols to store both customer and meter records directly inside standard and custom entities, thereby removing any dependency on live external systems.

b. Declarative Automation Strategy

The solution is built around a declarative architecture philosophy — favoring configuration over custom code — by making full use of native Salesforce Flow and Assignment Rules. This strategy removes the need for manual dispatch steps while ensuring the platform remains stable over time and easier to govern.

c. Role-Based Security

System visibility is segmented according to each user group's operational scope and responsibilities, guaranteeing that data access is appropriately controlled across the organization.

3.1.2 Security and Governance Framework

To safeguard database records against unauthorized changes and support long-term scalability, the future-state design establishes a multi-layered data access strategy. This

framework lays out the foundational governance pillars that will determine user visibility prior to the creation of explicit profile configurations.

a. Organization-Wide Defaults (OWD)

Private Baseline Restriction: Establishes a secure data boundary by restricting access to all records by default, preventing users from viewing client files they are not authorized to see.

b. Role Hierarchy Realignment

Vertical Reporting Roll-up: Automatically propagates record visibility upward through the management structure, enabling supervisors to maintain full operational oversight.

c. Functional Access Profiles

Role-Based Boundary Enforcements: Regulates feature access according to job responsibilities, drawing a clear line between administrative call desk functions and technical field-level entries.

3.2 Process Flow Diagrams

3.2.1 Future State TO-BE Process Flow

The redesigned future-state process introduces structured automation through Salesforce, aiming to replace manual spreadsheet management and accelerate information handoffs between roles.

- Step 1 (Intake): A customer contacts the support line to report an infrastructure disruption or service outage. The customer support agent picks up the call and launches the Salesforce Service Console.
- Step 2 (Synchronous Lookup): The agent enters the customer's unique identifier into the global search bar. Salesforce queries the indexed database and retrieves the associated Account, Contact, and asset information on a unified screen within 2 seconds (Resolution to Bottleneck B1).
- Step 3 (Logging): While still on the call, the agent confirms the customer's details, records the issue parameters, and clicks save to create a new Case record, thereby concluding the customer-facing interaction.

- Step 4 (Asynchronous Dispatch): The act of saving the Case record automatically triggers a background Record-Triggered Flow in Salesforce. The system generates a related Field_Visit__c record and dispatches a targeted push notification directly to the designated technician's mobile device (Resolution to Bottleneck B2).
- Step 5 (Execution): Upon receiving the mobile alert, the field technician proceeds to the specified coordinates, carries out the required physical repairs, and marks the status field as "Resolved" within the Salesforce Mobile App.
- Step 6 (Real-Time Closeout): The mobile status update activates a backend automation flow that transfers the technical notes, automatically sets the parent Case to "Closed", and instantly refreshes the executive KPI dashboards (Resolution to Bottleneck B3).

3.3 Gap Analysis

The table below compares the manual shortcomings identified in the legacy environment against the structured solutions developed for the Salesforce configuration.

Legacy Identified Gap (AS-IS)	Salesforce Optimized Solution (TO-BE)	Target Enterprise Business Value
Manual lookups in spreadsheets consumed up to 5 minutes per customer interaction.	Customer and asset records are natively structured with indexed lookup fields.	Reduces search time to under 2 seconds per call, cutting abandonment rates.
Case details were manually typed into WhatsApp or communicated over voice calls.	Automated assignment logic with Record-Triggered custom object creation handles routing.	Eliminates manual dispatch coordination, closing a 15% human error gap.
Field personnel logged technical parameters on handwritten paper forms.	Technicians capture resolution data natively through standard mobile page layouts.	Prevents information loss from field operations and removes paper-based overhead.

Job record updates were delayed 2 to 4 hours before reaching management.	Automatic case roll-up logic refreshes dashboards the moment a record is changed.	Gives leadership immediate, clean visibility into real-time operational KPIs.
--	---	---

Conclusion

This phase ensures that the technical solution is fully aligned with the organization's business objectives. It serves as the foundational reference for the system configuration and build activities planned for Milestone 4.
